Windows systems utility | Real source, interface previews and project decisions

I started with heat, power modes, and the state Windows actually applies.

The project combines a C# / WPF host with a WebView2 interface.

Public files include application source, build instructions and interface assets.

My work spans investigation, system design, implementation decisions and review.

AI and coding tools are part of my toolkit when they help the work.

Interface preview with sample state. It is not a physical telemetry measurement.

A switch needs a read-back

```
public static OperationResult Apply(string mode)
{
    mode = NormalizeMode(mode);
    if (!PlanGuids.ContainsKey(mode))
    {
        return OperationResult.Fail("Unknown power mode.", controlPath: ControlPath, requestedMo
    }

    var planGuid = GetGuidForMode(mode);
    if (planGuid == null)
    {
        return OperationResult.Fail(
            "The " + DescribeMode(mode) + " power plan is not installed.",
            "Neither the current nor the legacy plan GUID was found.",
            ControlPath,
            mode,
            verifiedMode: DetectActiveMode());
    }

    // Switching plans must not rewrite a user's existing processor settings.
    var result = RunPowerCfg("/setactive " + planGuid);
    if (result.ExitCode != 0)
    {
        return OperationResult.Fail("Power plan switch failed: " + CleanError(result.ErrorOutput
    }

    var verifiedMode = DetectActiveMode();
    if (verifiedMode != mode)
    {
        return OperationResult.Fail("Power plan change could not be verified.", "Expected " + mo
    }
    return OperationResult.Ok("Power mode verified: " + DescribeMode(mode) + ".", ControlPath, m
}

Hardware and firmware decide which controls are available.

Unsupported GPU switching is kept distinct from supported Windows power controls.

See the README and build documentation for requirements and current scope.
